Lecture

Getting caught up because of basically 2 missed days.

moar RM LUB.

case 1: c_1 short enough to fit all 3 releases in T_2 (fits S2 critical time zone).

case 2: c_1 too large to fit last release in T_2 (doesn't fit S2 critical time zone).

examine both and we can find a common upper bound.

two bounds and their intersection creates the LUB.

Utility isn't dependent on computation time here strictly because of previous assumptions.

why not use EDF all the time?

excess computation.
